March 2011

1.0 Introduction

AbiBow US Inc. (AbiBow) manufactures coated paper and market pulp at their Catawba, South Carolina facility. In late August 2003, AbiBow began operations of a new Fiberline and Bleaching System to comply with the pulp and paper Cluster Rule. The new Fiberline system allowed the facility to produce kraft pulp more efficiently and environmentally friendly. The fiberline was modified in 2006 to increase pulp quality and production. This permit application is for kraft mill upgrades to optimize the pulp yield.

The South Carolina Department of Health and Environmental Control (SCDHEC) application forms are contained in Appendix A.

This page intentionally left blank

2.0 Project Description

The optimization project will increase the yield from the kraft mill using the same amount of raw materials (wood and cooking liquor) to produce more tons of pulp. The project includes modifications to the kraft pulping system, evaporator system, and chlorine dioxide plant (part of the bleaching system).

No modifications to recovery furnaces, smelt dissolving tanks, lime kiln, causticizing area, or woodyard are necessary since no additional wood fiber or cooking liquor is required, and consequently no additional black liquor solids are generated.

2.1 Kraft Mill Pulping System

The modifications to the kraft pulping system will consist of the following:

- New oxygen mixer and booster pump
- New oxygen reactor (1B)
- Increased brownstock washing shower (wash) water

The kraft pulp mill will be modified to increase the yield from the digester by raising the Kappa and shifting more delignification from the digester to the oxygen delignification system. This will be accomplished by installing a third oxygen reactor, with the associated mixer, booster pump, and piping, between the existing No. 1 and No. 2 oxygen reactors.

These changes will reduce steam demand at the digester and yield more pulp from the same amount of wood and cooking liquor. The increased yield will lower the black liquor solids generated per ton of pulp and will also lower the liquor heating value. The increased wash water is required for oxygen delignification efficiency and generating more weak black liquor. The increased yield and change in Kappa will increase demand for chlorine dioxide in the bleaching system.

Based on the PSD construction permit issued in 2006 (2440-0005-DA), the kraft pulping system is projected to produce 1,825 air dried tons unbleached pulp (ADTUP) per day. The proposed modifications do not increase the projected future production beyond the level projected in construction permit DA. A pulping system process flow diagram is contained in Appendix B, as Figure B-1.

2.2 Kraft Mill Evaporator System

The modifications to the Kraft mill evaporator system will consist of the following:

- Replace existing No. 3 evaporator evaporative condenser (heat exchanger) with new surface condenser (heat exchanger)
- New No. 3 evaporator NCG gas cooler
- New No. 3 evaporator NCG ejector condensers
- New No. 3 evaporator hotwell
- No. 3 evaporator pump upgrades and replacements
- New No.1 evaporator liquor heat exchanger and transfer pump
- No. 1 evaporator pump upgrades

The evaporator modifications will increase the surface area for evaporation available to process the additional weak black liquor from the fiberline. The increased evaporation will require additional steam, which will be offset by the efficiency gained from the replacement of the No. 3 evaporator condenser, as well as improved heat transfer from the new No. 1 evaporator heat exchanger. A process flow diagram is contained in Appendix B, as Figure B-2.

2.3 Bleaching System (Chlorine Dioxide Plant)

The chlorine dioxide plant is part of the kraft bleaching system. The chlorine dioxide plant will be modified to increase production to support bleaching the additional pulp production. The modifications to the chlorine dioxide plant will consist of adding a filtrate separation system surge tank with associated pumps and piping. The addition of a filtrate separation system will

reduce the evaporation load in the generator to enhance process stability over the range of operating conditions and production rates.

The modifications are projected to increase production to 40 tons per day of chlorine dioxide. Based on the PSD construction permit issued in 2006 (2440-0005-DA), the bleaching system is projected to produce 1,752 air dried tons unbleached pulp (ADTUP) per day. The proposed modifications do not increase the projected future production of the bleaching system beyond the level projected in construction permit DA. A process flow diagram for the chlorine dioxide plant is contained in Appendix B, as Figure B-3.

2.4 Changes to Steam Demand

The proposed project is expected to result in a slight, but negligible reduction in mill steam demand. The proposed modifications to kraft pulping system are expected to reduce steam demand at the digester by approximately 3,982 pounds per hour. The additional weak black liquor from the kraft pulping system is expected to require approximately 9,909 pounds per hour of additional steam at the evaporators. The evaporator heat exchanger modifications are expected to reduce steam demand at the evaporators by approximately 7,237 pounds per hour. The bleaching system is expected to require approximately 1,302 pounds per hour of additional steam to process the additional pulp. The net effect of the project is a slight reduction in steam demand of approximately 8 pounds per hour.

2.5 Market Pulp Dryer (not modified)

The additional pulp available as a result of the proposed project is expected to be sold as market pulp. The pulp dryer will not be modified as a result of this project, so the projected actual emissions for the pulp dryer will be based on adding the additional production due to the project to the historical best month of production during the 24-month baseline. Market pulp is sold as machine dry tons (i.e., as is) since the purchaser adds water to repulp the product prior to converting into final products. The pulp dryer steam usage is not expected to change as a result

of the additional production because additional steam increases costs, so the moisture content of the market pulp will be allowed to increase slightly.

March 2011

3.0 Applicable Regulations

3.1 40 CFR Part 63, Subpart S (National Emission Standards for Hazardous Air Pollutants from the Pulp and Paper Industry)

The AbiBow Catawba mill is regulated by the Part 63 NESHAPs for the Pulp and Paper Industry (Subpart S). The kraft pulping system is already considered a new source under this regulation and meets all Subpart S requirements. The kraft mill evaporators are existing sources and are also regulated under Subpart S.

The MACT standards for kraft pulping and evaporator systems (63.443) allow AbiBow to select one of several options for treatment.

- Reduce total HAP emissions by 98 percent or more by weight;
- Reduce total HAP concentration at the outlet of the thermal oxidizer to less than 20 ppm by volume on a dry basis at 10 percent oxygen;
- Reduce total HAP emissions using a thermal oxidizer operating at minimum temperature of 1600°F with a minimum residence time of 0.75 second; or
- Reduce total HAP emissions by introducing high volume low concentration (HVLC) and low volume high concentration (LVHC) gases into the combustion zone of a boiler, lime kiln, or recovery furnace.
- Collect kraft pulping condensates (11.1 pounds of HAP per ton of pulp production) and reduce 92 % of HAP or remove 10.2 pounds of HAP per ton pulp (HAP measured as methanol)

In addition, the treatment device used to control HVLC gases must be operational a minimum of 96 percent of the operating time during the reporting period, excluding periods of startup, shutdown, or malfunction (SSM) (63.443(e)(2)). The LVHC gases are required to be incinerated 99 percent of the operating time, excluding SSM periods. AbiBow combusts the LVHC and HVLC gases in the two facility combination boilers. The kraft pulping condensates must be

collected and treated 90% of the time. AbiBow uses a condensate stripper to remove HAP from the wastewater.

The MACT standards for bleaching systems (63.445) allow AbiBow to select one of several options for treatment.

- Reduce chlorinated HAP emissions by 99 percent or more by weight;
- Reduce chlorinated HAP concentration at the outlet of the control device to less than 10 ppm by volume;
- Achieve a post control device chlorinated HAP mass emission rate of 0.002 pounds per ton of pulp.

Monitoring requirements have already been established in accordance with Cluster Rule 63.453(b).

3.2 40 CFR Part 60, Subpart BB (Standards of Performance for Kraft Pulp Mills)

The total reduced sulfur (TRS) emissions from the kraft digesting system and condensate stripper are regulated by 40 CFR 60, Subpart BB. The digester system and condensate stripper emissions are collected and burned in the combination boilers, meeting the control requirements under 60.283(1)(iii).

The pulp washing system uses a pressure diffusion washer, which is exempted from Subpart BB applicability (60.281(e)). However, the pressure diffusion washer vents to the blow tank, which is included in the digester system definition, so the pulp washing system TRS emissions are controlled.

The No. 1 and No. 3 evaporator sets are regulated under Subpart BB since they were modified (No. 1 evaporator) or constructed (No. 3 evaporator) following the applicability date. The evaporator system emissions are collected and burned in the combination boilers, meeting the control requirements under 60.283(1)(iii).

The other components of the kraft pulp mill (oxygen delignification and knotting and screening systems) are not regulated units under 40 CFR 60, Subpart BB. There are no requirements for bleaching systems in 40 CFR 60, Subpart BB.

3.3 South Carolina Regulation 62.5, Standard No. 1 (Emissions from Fuel Burning Operations)

Standard No. 1 does not apply because the project does not involve modifications to any fuel burning sources.

3.4 South Carolina Regulation 62.5, Standard No. 2 (Ambient Air Quality Standards)

The air dispersion modeling analyses described in Section 6 of this application address all applicable ambient air quality standards.

3.5 South Carolina Regulation 62.5, Standard No. 3 (Waste Combustion and Reduction)

Standard No. 3 does not apply because the project does not involve waste combustion as defined in the regulation.

3.6 South Carolina Regulation 62.5, Standard No. 4 (Emissions from Process Industries)

The processes being modified are currently subject to Standard No. 4.

3.7 South Carolina Regulation 62.5, Standard No. 5.1 (State LAER)

The project is not subject to the South Carolina Lowest Achievable Emission Rate (LAER) regulation because VOC emissions increase will not exceed 100 tons since the baseline date.

3.8 South Carolina Regulation 62.5, Standard No. 5.2 (Control of Oxides of Nitrogen)

Standard No. 5.2 does not apply because the project does not involve modifications to any sources of NO_X emissions.

3.9 South Carolina Regulation 62.5, Standard No. 7 (Prevention of Significant Deterioration)

The changes in emissions from the facility as a result of the proposed project were compared to the significant emission thresholds to determine which pollutants would require permitting under

the Prevention of Significant Deterioration (PSD) program. The net emission changes were evaluated on a baseline actual-to-projected actual basis for the following sources:

- Kraft mill pulping system (modified source)
- Kraft mill evaporator system (modified source)
- Kraft mill bleaching system (modified source)
- Pulp dryer (affected source)

AbiBow is considered a major stationary source under New Source Review (NSR) since it emits or has the potential to emit 100 tons per year or more of a regulated NSR pollutant as defined in SC Reg. 61-62.5, Standard No. 7. The Catawba Mill is located in the Charlotte-Gastonia-Rock Hill 8-hour ozone nonattainment area, and is also subject to nonattainment NSR permitting requirements in SC Reg. 61-62.5, Standard No. 7.1 for the pollutants NO_X and VOC. The proposed project is not considered major modification if it will not cause a "significant emissions increase" of a regulated pollutant as defined in Standards No. 7 and No. 7.1.

The emission increases for the proposed project were calculated based on the actual-to-projected-actual applicability test outlined in 61-62.5, Standard No. 7(a)(2)(c). In this test, a significant emissions increase is projected to occur if the sum of the difference between the projected actual emissions and the baseline actual emissions for each existing emissions unit equals or exceeds the significant amount for that pollutant. As allowed under the regulations, the emissions that the source could have accommodated prior to the proposed changes were excluded from the significant emission increase calculation.

The following formulae may be used for calculating the significant emission increase:

$$SEI = PAE - BAE - (CHAE - BAE)$$

where: SEI = significant emission increase

PAE = projected actual emissions

BAE = baseline actual emissions

CHAE = could have accommodated emissions

The projected actual emissions determined in accordance with Regulation 61-62.5, Standard No. 7(b)(41)(i) and (ii)(a) should consider all relevant information, including "the company's own representations", "the company's filings with the State and Federal regulatory authorities", and "compliance plans approved under the State Implementation Plan". The projected actual emissions for the kraft fiberline and bleaching system were established as part of PSD construction permit 2440-0005-DA, and therefore are consistent with the regulatory requirement. The future production projections remain unchanged as a result of the proposed project.

The baseline actual emissions are based on the highest average production for the modified emission units during a consecutive 24-month period during the previous ten years as described in SC Regulation 61-62.5, Standard No. 7(b)(4)(ii).

The emissions that the modified emission units "could have accommodated" are excluded from the project actual emissions, as allowed by SC Regulation 61-62.5, Standard No. 7(b)(41)(ii)(c). Since this project increases the pulp yield using the same amounts of raw materials (wood fiber and cooking chemicals), the "could have accommodated" emissions are based on the highest month production during the 24-month baseline period. This approach is consistent with the methodology used in PSD construction permit 2440-0005-DA, as well as a recent Region 4 policy memorandum issued March 18, 2010.

The PSD applicability for greenhouse gases (GHG) in South Carolina is based on the EPA Tailoring Rule. The South Carolina General Assembly granted SCDHEC the authority to implement the EPA Tailoring Rule in the Fall of 2010. The Tailoring Rule contains a two-part applicability test in which both parts must be satisfied for PSD to apply. In part one, the project increases of carbon dioxide (CO₂), methane (NH₄), and nitrous oxide (N₂O) are each compared to a significant increase threshold of zero. In part two, the aggregate CO₂ equivalent emissions are compared to a significant increase threshold of 75,000 tons.

Based on emission calculations summarized in Appendix A, sulfur dioxide (SO₂) will be subject to Prevention of Significant Deterioration (PSD) permitting requirements.

^{*} The project does not meet the greenhouse gas part 2 significant increase threshold for aggregate carbon dioxide equivalent emissions.

3.10 South Carolina Regulation 62.5, Standard No. 7.1 (Non-Attainment)

The AbiBow facility is located in the Charlotte/Gastonia/Rock Hill 8-hour Ozone non-attainment area. The changes in NO_x and VOC emissions from the facility as a result of the proposed project were compared to the significant emission thresholds to determine which pollutants would require permitting under the nonattainment new source review program. The project will not increase NO_x or VOC emissions more than the significant emission rates in Standard No. 7.1; therefore, the project will not be subject to non-attainment new source review for ozone.

3.11 South Carolina Regulation 62.5, Standard No. 8 (Air Toxics)

The project will not increase the maximum emission rate of any toxic air pollutant over previous compliance demonstrations with Standard No. 8.

3.12 South Carolina Regulation 62.70 (Title V)

This project will not increase the projected actual emissions above the levels already permitted in Title V Operating Permit 2440-0005. Furthermore, no changes to the currently permitted emission limits or monitoring, recordkeeping, and reporting requirements are anticipated. AbiBow will submit revised Title V permit application forms for these sources within one year of startup of the modified equipment. The revised Title V application will address monitoring, recordkeeping, and reporting requirements contained in the pulp and paper MACT standards.

4.0 Emissions Estimates

4.1 Kraft Mill Emissions

The emissions from the kraft pulp mill were estimated using industry emission factors from the National Council for Air and Stream Improvement (NCASI). The emission factors were previously approved by SCDHEC under construction permit DA. The only modification to these emission factors is the accounting for sulfur capture in the combination boilers. Due to the alkalinity of wood ash, the combination boilers will capture approximately 32.5% of the sulfur in the kraft mill non-condensable gases (NCG's) based on information from NCASI. The emission calculations for the pulping system are presented in Appendix C along with the expected sulfur capture in the combination boilers.

4.2 Kraft Pulp Bleaching System and Chlorine Dioxide Plant

The emissions from the kraft pulp bleaching system and chlorine dioxide plant were estimated using industry emission factors from the National Council for Air and Stream Improvement (NCASI). The emission factors were previously approved by SCDHEC under construction permit DA. The emission calculations for the bleaching system and chlorine dioxide plant are presented in Appendix E.

4.3 Kraft Pulp Bleaching System

The emissions from the kraft pulp bleaching system were estimated using industry emission factors from the National Council for Air and Stream Improvement (NCASI). The emission factors were previously approved by SCDHEC under construction permit DA. The emission calculations for the bleaching system are presented in Appendix F.

4.5 Market Pulp Production

The emissions from the kraft pulp mill were estimated using industry emission factors from the National Council for Air and Stream Improvement (NCASI). The emission factors were

previously approved by SCDHEC under construction permit DA. The emission calculations for the pulp dryer are presented in Appendix G.

5.0 BEST AVAILABLE CONTROL TECHNOLOGY ANALYSIS

New Source Review (NSR) regulations [South Carolina Regulation 62.5 Standard No. 7] requires that Best Available Control Technology (BACT) be applied to minimize the emissions of compounds from a new major source or a major modification of an existing major source in attainment and non-attainment areas, respectively. This section presents the BACT evaluation for SO₂. No other pollutants exceed the NSR significance levels as a result of the proposed project.

The kraft mill TRS gases are collected in the LVHC and HVLC systems and combusted in the combination boilers. These gases are required by federal regulations (MACT and NSPS) to be collected in the LVHC and HVLC systems, and although the primary purpose of the combination boilers is to produce steam for mill operations, the boilers also combust the LVHC and HVLC gases from the kraft mill.

Section 5.1 presents an overview of the top-down BACT approach used in this application, and the BACT analyses for SO₂ from the kraft mill pulping and evaporator system modifications is presented in Section 5.2.

5.1 Top-Down BACT Approach

BACT is defined in the Clean Air Act as an emissions limit based on the maximum degree of emissions reduction for each pollutant...which the permitting authority determines, on a case by case basis, taking into account energy, environmental, and economic impacts and other costs, is achievable for such facility through the application of production processes and available methods, systems, and techniques.... Four key aspects of the definition are worthy of notice:

- BACT is an "emissions limit" based on a control technology not the control technology itself; or, if technological or economic limitations on the application of measurement methodology to an emissions unit would not be feasible, a design, equipment, work practice, operation standard, or combination thereof may be prescribed.
- BACT takes into account various costs associated with implementing pollution controls: economic, environmental (air, water, or solid waste), energy, and other impacts.

- BACT includes and, in fact, focuses on "production processes" along with add-on controls.
- BACT is intended to be a case-by-case evaluation, implying individual case evaluations and decisions, not rigid, pre-set guidelines.

The top-down BACT approach starts with the most stringent (or top) technology that has been applied to the same unit at other similar emission source types and provides a basis for rejecting the technology in favor of the next most stringent technology or proposing it as BACT.

Step 1

The first step is to define the spectrum of process and/or add-on control alternatives potentially applicable to the subject emissions unit. The following categories of technologies are addressed in identifying candidate control alternatives:

- Demonstrated add-on control technologies applied to the same emissions unit at other similar source types;
- Add-on controls not demonstrated for the source category in question but transferred from other source categories with similar emission stream characteristics;
- Process controls such as combustion or alternate production processes;
- Add-on control devices serving multiple emission units in parallel; and
- Equipment or work practices, especially for fugitive or area emission sources where addon controls are not feasible.

A review of the RACT/BACT/LAER Clearinghouse (RBLC) is the first step in this process.

Step 2

The second step in the top-down approach is to evaluate the technical feasibility of the alternatives identified in the first step and to reject those that can be demonstrated as infeasible based on an engineering evaluation or on chemical or physical principles. The following criteria are considered in determining technical feasibility: previous commercial-scale demonstrations, precedents based on permits, requirements for similar sources, and technology transfer.

Step 3

The third step is an assessment and documentation of the emissions limit achievable with each technically feasible alternative considering the specific operating constraints of the emission

units undergoing review. After determining what control efficiency is achievable with each alternative, the alternatives are rank-ordered into a control hierarchy from most to least stringent.

Step 4

The fourth step is to evaluate the cost/economic, environmental, and energy impacts of the top or most stringent alternative. To reject the top alternative, it must be demonstrated that this control alternative is infeasible based on the impacts analysis results. If a control technology is determined to be technically infeasible or infeasible based on high cost effectiveness, or to cause adverse energy or environmental impacts, the control technology is rejected as BACT and the impact analysis is performed on the next most stringent control alternative. In analyzing economic cost effectiveness, the annualized control cost (in dollars per ton of emissions removed) was compared with commonly accepted values for cost effective emission controls.

Step 5

The fifth and final step in the analysis is the consideration of toxic pollutant impacts on the control alternative choice. Toxics concerns are usually important only if an adverse toxic emissions impact results from the selected alternative. As in step 4, if an adverse toxic emissions impact is determined, the alternative is rejected in favor of the next most stringent alternative.

5.2 Kraft Mill Sulfur Dioxide from TRS Combustion

The net increase in sulfur dioxide (SO₂) emissions from the proposed modification is the result of the increased throughput to the kraft mill. The non-condensable gases (NCG's) from the kraft mill are collected within the LVHC and HVLC collection system. Both collection systems are combusted in the No. 1 and No. 2 combination boilers to comply with NSPS Subpart BB.

Potential control technologies for SO₂ emissions include pre-combustion TRS controls or post-combustion add-on SO₂ control technologies. As part of the new kraft fiberline project in 2001, AbiBow determined that the installation of pre-combustion scrubbers within the HVLC system was technically infeasible due to the high flow conditions, the required pressure drop across the scrubbing system, and potential impact to the combustion controls required by NESHAP

standards. AbiBow currently uses a TRS caustic scrubber on the LVHC system prior to the combination boilers to reduce TRS and SO2 emissions prior to combustion.

5.2.1.1 Demonstrated Control Technologies

AbiBow has evaluated control technologies for sulfur dioxide emissions from the kraft mill through the review of the RBLC database, the South Coast Air Quality Management District's (AQMD) BACT Guidelines, and the EPA Clean Air Technology Center's technical bulletins or fact sheets.

The RBLC contained limited SO₂ determinations for modifications to existing kraft mill systems. A summary of the BACT determinations are listed in Table 5.1. BACT determinations for new equipment or sources were excluded from further evaluation.

The selected control technologies for existing kraft mill systems include collection and incineration in recovery/power boilers.

5.2.1.2 Potential Control Technologies

Emission control technologies potentially applicable to the removal or destruction of sulfur dioxide from the post-control air stream were initially evaluated based upon technical feasibility. Technologies determined to be technically infeasible were excluded from further evaluation. Control technologies evaluated include scrubbers and flue gas desulfurization.

5.2.1.2.1 Wet Scrubbers

Scrubbers involve the use of packed columns or trays to facilitate contact between either a water or chemical solution to facilitate the preferential absorption of pollutants from the air stream to scrubbant solution for collection, treatment, and disposal. According to the EPA (EPA-452/F-03-015), absorption (scrubbing) may be used for gaseous streams containing high VOC concentrations, especially for water soluble compounds such as methanol, ethanol, isopropanol, etc.

Scrubbers are more commonly employed for use in controlling low dust loadings or soluble inorganic vapors. Wet scrubbers are employed to remove SO₂ from exhaust streams with a control efficiency averaging 90 percent (EPA-452/F-03-012).

According to the EPA (EPA-452/F-03-012, EPA-452/F-03-015, and EPA-452/F-03-017), wet flue gas desulfurization (FGD) may be achieved using impingement or tray scrubbers. The spent scrubbing solution is filtered to remove the calcium sulfite/sulfate, and the solids are sent to a landfill for disposal.

Traditional wet scrubbers are designed to control air flow ranging between 1,000 and 100,000 standard cubic feet per minute. Inlet gas temperatures range from 4°C to 370°C. Exhaust flow rates from Combination Boiler No. 1 or No. 2 are more than double the traditional scrubber operating range, while the exhaust temperature shall be near the upper limit of the technology. Although SO₂ may be removed from the post-combustion stream, the cooling of the exhaust stream may result in a visible plume with a potential for equipment corrosion.

Due to the low SO₂ emissions generated from the combustion of non-combustible gases and the high volume of air flow from the combination boiler, the anticipated control efficiency for a wet scrubbing system is anticipated to achieve no more than 90 percent control.

5.2.1.2.2 Flue Gas Desulfurization (FGD) – Dry

Dry flue gas desulfurization (FGD) removes SO₂ by using a spray dryer to inject lime slurry into the flue gas. Within the flue gas stream, SO₂ and the lime slurry react to form calcium sulfite and calcium sulfate. The calcium sulfite/sulfate is then removed from the exhaust gases using an ESP or other particulate control device.

AbiBow currently employs the use of an electrostatic precipitator (ESP) to control particulate emissions from each combination boiler. Installing a dry FGD would result in the ESP collecting both fly ash from the bark combustion and calcium sulfite/sulfate from the spray dryer, requiring a larger ESP. The powerhouse at the AbiBow Catawba mill is "land locked" and has very limited space. To build a FGD system and larger ESP for each combination boiler, major demolition and construction activities would be required to create the necessary space. These include relocating the kraft mill condensate stripper, wood chip and bark storage piles, chip truck dumper, chip conveyors and transfer stations, utility pipe bridges, and several roads. Based upon the major demolition or construction requirements to employ FGD, AbiBow has determined that the dry FGD process is technically infeasible.

5.2.1.3 Control Technology Cost Estimates

Upon review of the RBLC and the NEET databases, AbiBow has determined the sole technology that is technically feasible for SO₂ control is a wet scrubber system following the No.1 and No. 2 combination boilers. The existing process configuration minimizes SO₂ emissions through the reduction of TRS from the LVHC system gases prior to combustion. The cost-effectiveness of

post-combustion controls was determined by dividing the incremental annual cost difference by the theoretical SO₂ emissions reduction in tons per year for the control option.

The capital costs for the installation of a wet scrubbing system were determined based upon vendor supplied information. Formulas as provided in Section 5.2 of the EPA Air Pollution Control Cost Manual, Sixth Edition (APCCM) do not account for the high volumetric air flow rate and are not applicable to equipment costs. Basic equipment costs for a wet scrubber system are based on the air flow and pollutant loading. The purchased equipment cost includes the equipment costs plus additional costs associated with instruments and controls, taxes, and freight. Additional costs, not specifically included in vendor information, have been estimated using formulas within the APCCM.

The total capital investment for the wet scrubber system is estimated based on a series of factors applied to the purchased equipment cost to obtain direct and indirect installation costs. These costs are then added to the purchased equipment cost to determine the total capital investment.

Direct annual costs include operating and supervisory labor, operating materials, replacement parts, maintenance labor and materials, electricity, and waste disposal. Typical labor rates and material cost determinations have been determined based on APCCM assumptions. APCCM states that typical operating labor requirements are one-half hour per shift for each scrubber system. It is assumed that the operators will work 548 hours per year, based on 8,760 operating hours per year and eight hours per shift. (8,760 hrs/yr ÷ 8 hrs/shift x 0.5 hr/shift). Based on APCCM, the supervisory labor cost is assumed to be 15 percent of operating labor cost. Maintenance labor is estimated to be 548 hours per year, based on 8,760 operating hours per year and eight hours per shift. (8,760 hrs/yr ÷ 8 hrs/shift x 0.5 hr/shift).

The electricity price of \$0.046 per kilowatt-hour was used in the electricity cost determinations. The annual cost of electricity is based on the inlet stream flow rate, pressure drop, and pump/blower size. This cost was determined using the formula found in the APCCM. The

scrubber system will also have water, scrubbing solution, and wastewater treatment costs. These costs have been determined using the formulas found in the APCCM.

Indirect annual costs have been determined for the scrubber system. These indirect costs include overhead, taxes, insurance, administrative costs, and capital recovery. Overhead costs are assumed to be 60 percent of operating and maintenance costs, as presented by APCCM. Taxes, insurance, and administrative costs are assumed to be four percent of the total capital investment. Capital recovery is determined using a factor based on an equipment life of 15 years and an interest rate of seven percent. This factor is then multiplied by the total capital investment.

This cost effectiveness of installing a SO₂ scrubber is based upon the annualized costs divided by the emissions reduction provided by the control technology. The estimated equipment costs for the scrubbing system is \$4,000,000 per unit which includes the control system design, stack design, and erection costs. Items not included within the estimate include electrical wiring, control systems, reagent storage/feed systems, utility connections, site preparations, footings/supports, and ducting to the scrubber system.

In order to achieve continuous control of SO₂ emissions, the cost estimate must include the capital cost for two scrubbers, since emissions are routed to either the No.1 or No. 2 combination boilers. However, the operating costs are based on only one scrubber being in use at any time. Using APCCM formulas, the total capital investment for two scrubber systems with supporting equipment has been estimated at \$15,400,000. When accounting for annual costs and capital recovery factors, the total annualized cost for the SO₂ controls is \$4,158,462.

Based upon the formation of 385.2 tons per year of SO₂ from the modified kraft pulping and evaporator systems and a control efficiency of 90 percent, the cost effectiveness of the control technology is \$11,994 per ton of pollutant removed, which is not cost effective.

The control technology will also generate large volumes of acidic wastewater for treatment within the existing system and may require supplemental heating of the exhaust gases to prevent the formation of a visible plume.

 Control System	SO ₂ Loading (tpy)	SO ₂ Outlet (tpy)	Percent Reduction	SO ₂ Emissions Reduction (tpy)	Total Annualized C (\$/yr)	ost (\$/ton)	
SO ₂ Scrubber (90%)	385.2	38.5	90.00%	346.7	\$ 4,158,462	\$ 11,994	

5.2.1.4 Selection of BACT

AbiBow has concluded that wet scrubbers are not a cost effective control methodology, and their use would result in increased wastewater treatment considerations and corrosion concerns. Due to the high operating temperatures, the water and caustic soda usage may increase significantly due to evaporation. Furthermore, the addition of a wet scrubber may impact boiler efficiency or controls.

Therefore, BACT for SO₂ emissions resulting from combustion of kraft mill TRS emissions in the No. 1 and No. 2 combination boilers to comply with NSPS subpart BB is continued use of the LVHC collection system TRS scrubber.

6.0 Air Quality Impact Analysis

Air dispersion modeling analyses for Class II areas around the facility will be prepared and submitted to DHEC under separate cover, following review and agreement on an air dispersion modeling protocol. Similarly, air dispersion modeling for appropriate PSD Class I areas will be discussed with the appropriate Federal Land Manager(s) and submitted under separate cover. DHEC will be provided with copies of PSD Class I area modeling and correspondence with the FLM(s).

This page intentionally left blank

7.0 Additional Impacts Analysis

The additional impacts of the proposed modification on growth, soils and vegetation, and Class II visibility will be addressed in the air dispersion modeling analysis submitted under separate cover.

- D) Assumed TRS (as S) converted to H2S based on molecular weight.
- E) Assumed 100% conversion of TRS (as S) to SO2 in Combination Boiler.
- F) Emission factor from NCASI Technical Bulletin 884, Table 4.2 adjusted from #/ton chips to #/ADTP assuming 50% yield.
- G) Emission factor adjusted from VOC as carbon to total VOC based on molecular weight of predominate VOC species.
- I) Assumed 32.5% sulfur capture in combination boiler wood ashes per NCASITB 640, Figure 11.
- J) Emission factor assuming 100% conversion of carbon (VOC as C and CO) into carbon dioxide from NCG combustion.
- K) Emission factor based on ratio of emission factors for solid biomass combustion in EPA MRR, Table C-1 and C-2.
- L) Emission factor based on GWP in EPA MRR, Table A-1.

NOTES:

Emission factor of zero (0.00E+00) indicates pollutant was tested for and not detected above quantitation limit.

Actual production is calendar year 2005 production rate.

Maximum production is permitted production rate.

Total reduced sulfur emission are the sum of emissions of hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and dimethyl disulfide.

Process variability factors for TRS and VOC reflect assumed minimum percent reductions (99% and 98%) due to NCG combustion in combination boilers.

Process variability factor for SO2 reflects assumed minimum percent reduction (32.5%) due to sulfur capture by wood ash in combination boilers.

Total 112(b) Hazardous Air Pollutants					7.2	6.0	6.7

- A) Median emission factors from NCASI Technical Bulletin No. 858, Table 3.
- B) Emission factors from New Fiberline PSD Permit Application
- C) Sum of dimethyl disulfide, dimethyl sulfide, hydrogen sulfide, and methyl mercaptan emissions
- D) Assumed TRS (as S) converted to H2S based on molecular weight.
- E) Assumed 100% conversion of TRS (as S) to SO2 in Combination Boiler.
- F) Sum of dimethyl disulfide, dimethyl sulfide, hydrogen sulfide, and methyl mercaptan emissions.
- G) Emission factor adjusted from VOC as carbon to total VOC based on molecular weight of predominate VOC species.
- I) Assumed 32.5% sulfur capture in combination boiler wood ashes per NCASITB 640, Figure 11.
- J) Emission factor assuming 100% conversion of carbon (VOC as C and CO) into carbon dioxide from NCG combustion.
- K) Emission factor based on ratio of emission factors for solid biomass combustion in EPA MRR, Table C-1 and C-2.
- L) Emission factor based on GWP in EPA MRR, Table A-1.

NOTES:

Emission factor of zero (0.00E+00) indicates pollutant was tested for and not detected above quantitation limit.

Actual production is calendar year 2005 production rate.

Maximum production is permitted production rate.

Total reduced sulfur emission are the sum of emissions of hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and dimethyl disulfide.

Process variablity factors for TRS and VOC reflect assumed minimum percent reductions (99% and 98%) due to NCG combustion in combination boilers.

Process variability factor for SO2 reflects assumed minimum percent reduction (32.5%) due to sulfur capture by wood ash in combination boilers.

NOTES:

Emission factor of zero (0.00E+00) indicates pollutant was tested for and not detected above quantitation limit.

Actual production is calendar year 2005 production rate.

Maximum production is permitted production rate.

Total reduced sulfur emission are the sum of emissions of hydrogen sulfide, methyl mercaptan, dimethyl sulfide, and dimethyl disulfide.

Process variability factors for TRS and VOC reflect assumed minimum percent reductions (99% and 98%) due to NCG combustion in combination boilers.

Process variability factor for SO2 reflects assumed minimum percent reduction (32.5%) due to sulfur capture by wood ash in combination boilers.

Sulfur Capture in Combination Boilers

The National Council for Air and Stream Improvement (NCASI) has documented the inherent sulfur capture in combination bark boilers, due to the alkalinity of the boiler ashes. The sulfur capture is a function of the sulfur to wood ratio in the boiler. The percent of sulfur captured in wood-fired combination boilers from NCASI technical bulletin 640 is:

$$Y = 122.34 * X^{0.50}$$

where: Y = percent sulfur captureX = ton wood residue/lb sulfur in combined fuel

Average sulfur from No. 6 Oil firing (boilers do not burn maximum oil and wood simultaneously):

No. 6 Oil sulfur content = 2.1%

CB1 Oil in $2009 = 852 \text{ gal/day} \times 7.88 \text{ lb/gal} \times 0.021 \text{ lb S/gal} = 141 \text{ lb/day}$

CB2 Oil in $2009 = 1{,}142 \text{ gal/day} \times 7.88 \text{ lb/gal} \times 0.021 \text{ lb S/gal} = 189 \text{ lb/day}$

Maximum sulfur from TDF firing:

TDF sulfur content = 1.23%

CB1 = $36.0 \text{ tons/day} \times 2,000 \text{ lb/ton} \times 0.0123 \text{ lb S/lb TDF} = 886 \text{ lb/day}$

 $CB2 = 36.0 \text{ tons/day} \times 2,000 \text{ lb/ton} \times 0.0123 \text{ lb S/lb TDF} = 886 \text{ lb/day}$

Maximum sulfur from NCG burning:

HVLC from 2009 AEI = 0.26 lb TRS as S/ADTP

LVHC from 2009 AEI = 0.82 lb TRS as S/ADTP (including 50% reduction from TRS scrubber)

SOG from 2009 AEI = 3.1 lb TRS as S/ADTP

NCG = SOG + LVHC + HVLC = 3.1 + 0.82 + 0.26 = 4.18 lb S/ADTP

 $1,825 \text{ ADTP/day} \times 4.18 \text{ lb S/ADTP} = 7,629 \text{ lb/day}$

Sulfur input to combination boilers:

CB1 = 141 + 886 + 7.629 = 8.656 lb/day

CB2 = 189 + 886 + 7,629 = 8,704 lb/day

Sulfur Capture:

CB1 average wood in 2009 = 616 tons/day

CB1-X = 616 tons wood/day \div 8,656 lb S/day = 0.071 CB1-Y = $122.34 \times 0.071^{0.50} = 122.34 \times 0.266 = 32.5\%$ sulfur capture

CB1 average wood in 2009 = 827 tons/day

CB2-X = 827 tons wood/day ÷ 8,704 lb S/day = 0.095 CB2-Y = $122.34 \times 0.095^{0.50}$ = 122.34×0.31 = 37.9% sulfur capture

March 2011 C-16 The emissions of SO₂ resulting from the combustion of pulp mill non-condensable gases (NCG's) will be reduced by 32.5% due to sulfur capture by the wood ash in the combination boilers.

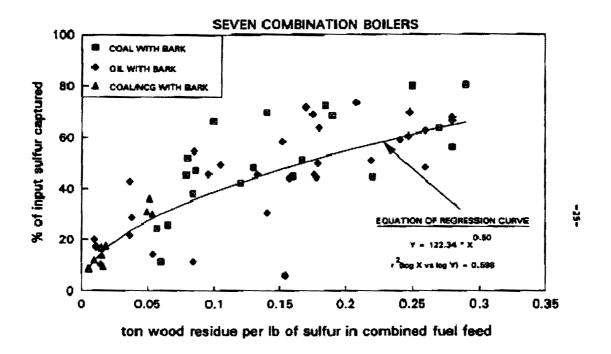

FIGURE 11 SUMMARY OF GAS-SOLED SULFUR CAPTURE IN COMBINATION BOILERS

APPENDIX F Historical Production Rates

The historical monthly production rates used to determine the could have accommodated emissions are presented in the table below. These production rates represent the production capabilities of the equipment prior to the proposed project. This is the currently accepted approach by EPA Region 4 as outline in the Mach 18, 2010 memo (attached).

UNITED STATES ENVIRONMENTAL PROTECTION AGENCY

REGION 4 ATLANTA FEDERAL CENTER 61 FORSYTH STREET ATLANTA, GEORGIA 30303-8960

MAR 1 8 2010

Mark Robinson Plant Manager Georgia-Pacific Wood Products LLC Highway 13 North Columbia, Mississippi 39429

Dear Mr. Robinson,

On December 1, 2009, the Mississippi Department of Environmental Quality (MDEQ) forwarded to the Environmental Protection Agency (EPA) your 502(b)(10) change request dated November 16, 2009. Please note that Mississippi regulations at APC-S-6 Section IV.F require that facilities provide EPA as well as MDEQ with written notification in advance of the proposed changes. In the future, you must provide EPA with a copy of any 502(b)(10) changes.

On December 2, 2009, EPA notified MDEQ via e-mail about concerns regarding Georgia Pacific's use of the "demand growth exclusion" in 40 CFR 52.21(b)(41)(ii)(c) and whether the "Vortex Burners" project qualified as a 502(b)(10) change. On December 14, 2009, representatives from Georgia Pacific met with EPA Region 4 to discuss the 502(b)(10) change request and provided additional information regarding the project.

After further review and consideration, and contingent on the information submitted being accurate and complete, EPA acknowledges that Georgia Pacific's use of the "demand growth exclusion" for calculating applicability of the Prevention of Significant Deterioration (PSD) permitting requirements is adequate and the project does qualify as a 502(b)(10) change. However, we have some points of clarification regarding statements made on the 502(b)(10) change request letter.

We acknowledge that Georgia Pacific may use the highest demonstrated average monthly operating level during the baseline period as an approximation of the level of operation that the units "could have accommodated" during the baseline period. However, EPA disagrees with the statement that Georgia Pacific "...does not accept this as the limit on excludable emissions during the baseline..." and the statement that the excludable amount under the "demand growth exclusion" is "...the highest amount that the unit could have legally and physically emitted during the baseline..." For PSD applicability purposes, the concept of emissions that "could have been accommodated" is relevant only in conjunction with the source's calculation of "projected actual emissions." That is, once the projected actual emissions from the source following the proposed project have been determined, the source may exclude from the projection "that portion of the unit's emissions following the project that an existing unit could have

Internet Address (URL) • http://www.epa.gov Recycled/Recyclabie • Printed with Vegetable Oil Based Inks on Recycled Paper (Minimum 30% Postconsumer)

April 2011 F-2

accommodated" during the baseline period, and "that are also unrelated to the particular project." See 40 CFR 52.21(b)(41)(ii)(c). Accordingly, before any given emissions may be excluded under 40 CFR 52.21(b)(41)(ii)(c) on the basis that they result from future demand growth, those emissions must first be part of the projected actual emissions based on "all relevant information" [see e.g., 40 CFR 52.21(b)(41)(ii)(a)] used to make the emissions projection.

In summary, although we do not agree with some of the statements made by Georgia Pacific in the 502(b)(10) change request as explained above, based on the information submitted, we agree with Georgia Pacific's use of the "demand growth exclusion" for determining PSD applicability for the "Vortex Burners" project. Since the "Vortex Burners" project is not considered a Title I modification, and does not exceed emissions allowable under the permit, the change qualifies as a 502(b)(10) change. If you have any questions, you may contact Heather Abrams at (404) 562-9185 or Yolanda Adams at (404) 562-9214.

Sincerely,

Gregg M. Worley

APPENDIX H

Coated Paper Production Rates

The Catawba Mill manufactures coated paper grades No.3, No. 4, and No. 5 for a wide variety of commercial printing applications, using various blends of kraft pulp and TMP. The production of coated paper is market driven, and depends on the specific grades of coated paper ordered by customers. The excess kraft pulp not required for coated paper production is available for market pulp manufacturing on the pulp dryer.

The proposed project will not change the market demand for coated paper grades manufactured at the Catawba Mill. The proposed project will increase kraft pulp production, resulting in more excess kraft becoming available for market pulp in the future.

A recent illustration of this effect is evident in the mill production data from 2009. During the period from March through August 2009, coated paper production on the No. 1 Paper Machine was curtailed due to weak market demand, and the market pulp production on the pulp dryer was correspondingly higher. In September 2009, coated paper production returned to normal levels on the No. 1 paper machine. However, the higher market pulp production was sustained through September 2009 due to the peak in kraft mill production during the month.

APPENDIX I

Proposed BACT Limit for SO2

BACT for SO₂ emissions resulting from combustion of kraft mill TRS emissions in the No. 1 and No. 2 combination boilers to comply with NSPS subpart BB is continued use of the LVHC collection system TRS scrubber. The proposed BACT limit for SO2 from the modified kraft pulping and evaporator systems is 385.2 tons per year.

April 2011 I - 1

APPENDIX J Air Dispersion Modeling Analysis

Air Quality Modeling Analysis

1.0 Introduction

AbiBow US Inc. (AbiBow) manufactures coated paper and market pulp at their Catawba, South Carolina facility. This air dispersion modeling analysis was prepared in support of a Prevention of Significant Deterioration (PSD) permit application for a proposed kraft mill optimization project at the Catawba Mill. This PSD air dispersion modeling analysis describes the modeling methodologies that were utilized to complete air quality impact analyses associated with the PSD permit application.

This modeling analysis was conducted in a manner consistent with the approved Air Dispersion Modeling Protocol and follow-up discussions with SCDHEC and EPA, incorporating the most recent modeling guidance generally available at the time of submission.

1.1 Project Description

The optimization project will increase the yield from the kraft pulp mill using the same amount of raw materials (wood and cooking liquor) to produce more tons of pulp. A complete project description is provided in Section 2 of the PSD permit application.

1.2 PSD Applicability

AbiBow is considered a major stationary source under New Source Review (NSR) since it emits or has the potential to emit 100 tons per year or more of a regulated NSR pollutant as defined in SC Reg. 61-62.5, Standard No. 7. The proposed project is not considered major modification if it will not cause a "significant emissions increase" of a regulated pollutant as defined in Standard No. 7.

Based on the emission calculations from Section 4 of the PSD permit application, the pollutant sulfur dioxide (SO₂) will be subject to Prevention of Significant Deterioration (PSD) permitting requirements. Therefore, this is the only pollutant addressed in this PSD air dispersion modeling analysis.

April 2011

1.3 South Carolina Standard No. 2, Standard No. 7, and Standard No. 8

The air dispersion modeling demonstration for South Carolina Standard No. 2, Standard No. 7, and Standard No. 8 pollutants for the Catawba Mill currently on file with SCDHEC is based on the maximum short-term emission rates for each source. The proposed modification does not increase the short-term emission rates previously modeled from any sources.

South Carolina Standard No. 2 does not currently require modeling for the 1-hour SO_2 and 1-hour NO_X standards. Since the project is not subject to PSD permitting requirements for $PM_{2.5}$ and previously modeled PM_{10} emissions from the Catawba Mill are not increasing as a result of the proposed modification, South Carolina does not require modeling $PM_{2.5}$ at this time. Therefore no additional modeling for South Carolina is required for this application.

2.0 AIR QUALITY IMPACT ANALYSIS

2.1 Area Description and Classification

The AbiBow Catawba Mill is located at 5300 Cureton Ferry Road in Catawba, South Carolina in York County. The approximate UTM coordinates are Zone 17, 510.014 km East, and 3,855.589 km North at an elevation of approximately 532.5 feet above mean sea level. The land-use within three kilometers of the facility is primarily forest and/or water surfaces. Therefore, the area is classified as rural for air dispersion modeling purposes. A U.S.G.S map showing the location of the facility and surrounding areas is provided in Attachment 1.

2.2 Air Dispersion Model Selection

URS perform the modeling analyses using the most recent version of the EPA preferred AERMOD computer dispersion model, Version 09292. AERMOD was used to model emissions to estimate concentrations at the mill fence line and beyond. The modeling analyses was performed using meteorological data to determine maximum concentrations and corresponding receptor locations for each modeled compound and respective averaging periods. The AERMOD modeling options that were used include the following:

- Calculation of average concentrations
- Regulatory default options

Final plume rise

April 2011

- Stack-tip downwash
- Buoyancy-induced dispersion
- Calms processing routine
- Default wind profile exponents
- Default vertical potential temperature gradients
- "Upper Bound" Values for supersquat buildings
- No exponential decay

2.3 Meteorological Data

A five (5) year meteorological data set was used to execute the air dispersion modeling analyses. The most recent, readily available five year meteorological data set (2002-2006) recommended by SCDHEC is Charlotte, NC surface meteorological data and Greensboro-High Point, NC, upper-air data.

The Charlotte/Douglas International Airport is located approximately 40 kilometers north of the Catawba Mill. The area surrounding the airport is gently rolling hills, similar to the area surrounding the Catawba Mill. The representativeness of the Charlotte meterological data for use at the Catawba Mill was qualitatively reviewed based on the surface roughness, Bowen ratio, and albedo of each location.

The surface roughness parameter is related to the obstructions to wind flow in the immediate vicinity (1-kilometer) of the measurement or modeling site. The meteorological tower at the airport is located in the vicinity of several aircraft hangars and warehouses, with the runways on the opposite sides of these structures some distance away. This is somewhat similar to the Catawba Mill, which also has large buildings on-site, as well as a large expanse of surface water some distance away from the main production area. Although the two sites have large buildings nearby, the surface roughness of airport sites is generally lower than industrial sites. At large airports like Charlotte/Douglas, with numerous large buildings and aircraft hangars on one side of the airport, and grass and trees on the other side of the airport, the surface roughness can vary significantly even within the airport boundaries.

The Bowen ratio and albedo are related to the land use patterns within ten kilometers of the measurement or modeling site. The land use in the eastern semi-circle from the airport is

April 2011 J - 3

characterized by by mixed forest, industrial, and low intensity residential land uses, gradually becoming more dense toward Uptown Charlotte, located approximately 10 kilometers east of the airport. The western semi-circle is primarily mixed forest land and Lake Wylie, with scattered pockets of residentuial and industrial, but much less than the eastern semi-circle. The area surrounding the Catawba Mill is primarily mixed forest, evergreen forest, or agricultural land, with some water surface and some residential areas.

The differences in Bowen ratio and albedo between Charlotte/Douglas and the Catawba Mill are primarily related to the difference in agricultural and residential land uses. However, both locations have a large percentage of forest within 10 kilometers, and the surface roughness is probably a more significant difference between the two sites.

In order to address any potential concerns regarding the representativeness of the Charlotte/Douglas airport data, a second five (5) year meteorological data set was processed by SCDHEC using the surface characteristics of the area surrounding the Catawba Mill. The principle difference between the two sites is expected to be the surface roughness within 1 kilometer.

Both data sets were executed individually for each year and maximum predicted concentrations for the worst-case year was reported in the modeling results for comparison to the PSD Significant Impact Levels (SILs), PSD Significant Monitoring Concentrations (SMCs), NAAQS, and PSD increments.

2.4 Good Engineering Practice (GEP) Stack Height Analysis

GEP analysis was performed for all emission sources subject to modeling analysis in order to determine if wake effects and downwash options need to be selected in the computer model. The GEP analysis was performed using Version 4/21/04 of the EPA Building Profile Input Program for Plume Rise Model Enhancements (BPIPPRM). BPIPPRM is a PC-based program designed to incorporate the concepts and procedures expressed in the <u>Good Engineering Practice (GEP)</u> <u>Technical Support Document</u>, building downwash guidance, and other related references that

April 2011 J - 4

correctly calculate building heights and projected building widths for simple, multi-tiered, and groups of structures in the AERMOD model.

2.5 Modeled Emission Rates

The source emissions inventory and stack parameters from the most recent complete modeling analysis for the mill (July 2006) was reviewed and updated to reflect current stack parameters and emission rates for all modeled sources and pollutants. For the significant impact area modeling, only the actual emissions increases from the proposed project was modeled.

The emission increase for PSD significant impact modeling purposes is based on the actual emissions prior to the change and the maximum emissions following the change. As mentioned previously, the maximum SO₂ emissions from the Catawba Mill are not increasing as a result of the project. For the annual averaging period the actual average emissions will be modeled, based on the average production during the baseline period. For the short-term averaging periods (1-hour, 3-hour, and 24-hour), EPA and SCDHEC allow using the maximum actual daily emissions, based on the highest daily production during the baseline period.

Attachment 2 contains the actual daily production rates during the baseline period for the kraft pulp mill (the only modified source of SO₂ emissions). Attachment 3 contains the emission calculations showing the annual and short-term increases in SO₂ emissions due to the project.

2.6 Model Receptor Grid

The model receptor grid is similar to the grid in the July 2006 modeling analysis, and includes the AbiBow property line, the property of one neighboring facility and a railroad line crossing the property (both defined by EPA as ambient air), and off-site receptors. Property-line receptors were placed at approximately 50-meter intervals for the adjacent facility, the railroad line crossing the western side of the production area, and AbiBow's property line.

The off-site receptors are spaced at 100-meter intervals out to a distance of approximately 1 kilometer from the stacks, 250-meter intervals out to a distance of approximately 3 kilometers, and at 500-meter intervals out to approximately 7 kilometers. Terrain elevations for each

April 2011 J - 5

receptor were determined from USGS topographic maps using AERMAP. In accordance with SCDHEC modeling guidelines, NED data required for calculation of base elevations in AERMOD was obtained from http://seamless.usgs.gov/website/seamless/viewer.htm.

The main production area at the Catawba Mill, which includes the powerhouse, was assigned a base elevation of 532.5 feet above mean sea-level based on the mill survey. The mill plot plan has been included in Attachment 4.

2.7 Model Source Groups

The sources with SO₂ emissions changing as a result of the proposed project were modeled for comparison to the significant impact levels and pre-construction monitoring exemption levels. The incineration of kraft pulp mill non-condensable gases (NCG's) in the two combination boilers at the Catawba Mill is the only source of SO₂ due to the proposed project. The previous air dispersion modeling analyses indicated that combination boiler No. 1 produces a slightly higher impact than combination boiler No.2. Therefore, the kraft mill NCG's were modeled from model source NETNCG1. The modeled stack parameters as well as the annual and short-term modeled emission rates are presented in Table 1.

Table 1
Stack Parameters and Emission Rates

Model	Model	SO ₂ Emissions		Height		Diameter		Temperature		Flow Rate	
Source	Number	lb/hr	tpy	ft	m	ft	m	°F	K	ft/sec	m/sec
Combination Boiler No. 1 – NCG Gases	NETNCGI	1.07	303.5	228	69.5	10	3.05	363.8	457.5	47.2	14.4

2.8 Significant Impact Area Modeling

The first phase of the modeling analysis involved determining if the proposed changes at the facility subject to PSD review will have a significant impact on air quality. This was determined by modeling the change in emissions of SO₂, the only PSD subject pollutant due to the proposed project.

Results of the significant impact modeling were then used to determine if NAAQS or PSD increment modeling is required. The predicted maximum concentrations for SO₂ were compared to the EPA significant impact levels (SIL's) for each averaging period to determine the significant impact area (SIA) for the proposed project. The SIA is the distance to the farthest model receptor with a significant impact.

The recently promulgated 1-hour SO₂ NAAQS does not have published SIL's. For the 1-hour averaging period, the SCDHEC interim SIL of 10 μ g/m³ and the EPA interim SIL of 3 ppb (7.8 μ g/m³) were considered.

As shown in Table 2, the significant impact levels were not exceeded at any receptor for any averaging period as a result of the proposed project. Therefore, the proposed project does not have a significant impact on air quality, and no further modeling demonstrations are required for the PSD permit application.

2.9 Preconstruction Monitoring Exemption

Preconstruction ambient monitoring data may be required for each criteria compound subject to review under the PSD regulations if the maximum predicted concentration exceeds the PSD Ambient Monitoring Exemptions Levels. The maximum predicted concentrations are based on the results from the Significant Impact Analysis.

The maximum modeled SO₂ concentrations from the Significant Impact Analysis were compared to the PSD Monitoring Exemption Levels (significant monitoring concentrations) in Table 3 to determine if preconstruction monitoring data must be supplied.

Table 3
PSD Significant Monitoring Concentrations

Pollutant	Averaging Period	SMC μg/m³	MET File Set	Impact μg/m³
SO_2	24-HR	13.0	CLT/Douglas	0.049
	24-NK	13.0	CLT/Catawba	0.062

The predicted maximum 24-hour SO₂ concentration from the SIA modeling is below the corresponding SMC. Therefore, preconstruction ambient monitoring data is not required for the proposed project.

3.0 Growth Impacts

The proposed changes to the facility will not result in any significant growth. The site has been operating for over forty years. The proposed modifications will not add to employment at the site. The increased kraft pulp production will not change the wood and chemical shipments to the facility, and market pulp shipments from the site will only increase slightly. However, since much of the market pulp is shipped by rail, the secondary emissions associated with shipments from the site are not expected to increase significantly. Therefore, no significant growth impacts are expected from the proposed project.

3.1 Soils and Vegetation Impacts

The proposed project is only subject to PSD review for SO_2 . The modeled SO_2 emissions increase due to the proposed project has no significant impact (SIA = 0.0 km). Therefore, no significant impact on soils and vegetation is expected to result from the proposed project.

4.0 Class II Visibility Analysis

The proposed project is only subject to PSD review for SO_2 . The modeled SO_2 emissions increase due to the proposed project has no significant impact (SIA = 0.0 km). Therefore, no significant impact on Class II visibility is expected to result from the proposed project.

5.0 PSD Class I Areas

The Catawba Mill is located within 200 kilometers of several PSD Class I areas. Each Class I Area within 200 kilometers was screened using the Q/D analysis recommended in FLAG2010 to determine the anticipated need for evaluating Air Quality Related Values (AQRV's).

The net emission increases from the proposed project are 124.8 tons per year (tpy) of SO_2 , 15.8 tpy of NO_X , and 0.1 tpy of $PM_{2.5}$, for a total emissions increase of 140.7 tpy. Table 4 shows the total project emissions, the approximate distance to each Class I area within 200 km, and the calculated Q/D.

Table 4

AQRV Screening Criteria

Class I Area	Distance (km)	Total Project Emissions (tpy)	Q/D	Q/D Screening Level
Linville Gorge	140	140.7	1.0	10
Shining Rock	180	140.7	0.8	10
Great Smoky Mountains	216	140.7	0.7	10
Cape Romain	230	140.7	0.6	10

Although modeling for AQRVs is not anticipated based on FLAG2010, Class I Increment modeling was performed since the proposed project is subject to PSD requirements for SO₂.

The initial PSD Class I significant impact modeling used AERMOD with a special polar grid. The polar grid receptors were placed in an arc at a distance of 50 kilometers downwind in the direction of each Class I area along 1 degree radials. The maximum modeled concentration for each pollutant and averaging period was compared to Class I SILs to determine the need for additional modeling with CALPUFF.

As shown in Table 5, the predicted impacts from the proposed project at 50 kilometers downwind using AERMOD will not exceed the Class I SIL's at any Class I Areas. Based on these results, additional CALPUFF modeling would not be expected to produce significant impacts at any Class I Areas.

Table 5A
PSD Class I Area SO₂ Impacts
Charlotte-Douglas Airport Pre-Processed MET Files

	Anı	nual	3-1	our	24-hour	
Class I Area	SIL	Impact	SIL	Impact	SIL	Impact
	μg/m ³

Great Smoky Mountains	0.1	0.0130	1.0	0.0185	0.2	0.0351
Linville Gorge	0.1	0.0130	1.0	0.0210	0.2	0.0039
Shining Rock	0.1	0.0105	1.0	0.0210	0.2	0.0039

^{*} EPA has not established PSD Class I significant impact levels for the 1-hour averaging period.

Table 5
PSD Class I Area SO₂ Impacts
Charlotte-Catawba Pre-Processed MET Files

	Anr	ıual	3-h	our	24-hour	
Class I Area	SIL	Impact	SIL	Impact	SIL	Impact
	μg/m³	μg/m ³	μg/m³	μg/m³	μg/m³	μg/m ³
Cape Romain	0.1	0.0128	1.0	0.0082	0.2	0.0021
Great Smoky Mountains	0.1	0.0117	1.0	0.0152	0.2	0.0028
Linville Gorge	0.1	0.0142	1.0	0.0152	0.2	0.0028
Shining Rock	0.1	0.0071	1.0	0.0152	0.2	0.0026

^{*} EPA has not established PSD Class I significant impact levels for the 1-hour averaging period.

It should also be noted that in December 2005, a CALPUFF modeling analysis addressing AQRV's and Class I Increments for these Class I areas was submitted to SCDHEC and the appropriate Federal Land Managers in support of a PSD permit application. The 2005 PSD application was for project emission increases of 247 tpy of SO₂, 134 tpy of NO_X, and 44 tpy of PM₁₀. Although the Q/D criteria were not available in 2005, the Q/D value from the 2005 application for Linville Gorge would have been 3.0. The results of the 2005 CALPUFF modeling analyses indicated no significant impacts to any AQRV's or PSD Increments at

Linville Gorge, Shining Rock, or Cape Romain. A summary of the 2005 CALPUFF analysis is provided in Attachment 5.

In July 2006, CALPUFF modeling was again performed for the Catawba mill sources subject to the Best Available Retrofit Technology (BART) regulations. Although the modeled emission rates for the BART-eligible sources were much higher than the 2005 PSD modeling, these higher emissions did not cause or contribute to any visibility impairment at nearby Class I areas. A summary of the 2006 CALPUFF analysis is provided in Attachment 6.

9.0 Model Results

The AERMOD, BPIPPRM, and model input and output files for the modeling analysis will be provided on a disc(s). AERMOD will be re-executed and re-submitted if necessary when the newest version supporting the one-hour SO₂ standard is available from the modeling software vendor used for this analysis.

CALPUFF Modeling Summary December 2005

Class I Area Modeling Results:

A Class I analysis was performed to determine the facility's impact on two Class I areas, namely, the Linville Gorge and Shining Rock Forest Service Wilderness Areas. The Class I analysis was conducted using the CALPUFF model in a refine mode based on modeling procedures discussed in a September, 2005 modeling protocol prepared by URS Corporation and written comments on the protocol provided by the Forest Service in a letter to the South Carolina Department of Health and Environmental Control dated November 17, 2005. A copy of the letter from the Forest Service is presented in Appendix E.

The results of the CALPUFF modeling analysis are summarized in Table 6. As shown, the predicted air quality impacts for deposition, regional haze and pollutant concentration are well below the applicable regulatory threshold values. Based upon results from this refined level CALPUFF modeling analysis, no adverse air quality impacts are predicted to occur in either Class I area. Consequently, no further Class I area analyses are required and this component of the PSD application submittal is complete.

Attachment 6 CALPUFF Modeling Summary July 2006

7.1 CALPUFF Modeling Results

The CALPUFF modeling results are summarized in Tables 7-1 and 7-2. The format of the tables was taken directly from the VISTAS common protocol. The modeling results clearly indicate that the Bowater BART eligible units do not cause or contribute to any visibility impairment in any of the nearby Class I areas. Therefore, based on the modeling information and results presented in this report, Bowater requests that the SCDHEC review this modeling submittal for completeness and respond with a letter stating that the Bowater facility is exempt from any additional BART regulatory requirements.

Included with this report is a CD that includes the full set of CALPUFF inputs and output files as well as other post-processor files used to generate the results. As indicated in the VISTAS common protocol, regional CALPUFF-ready meteorological files are not being supplied. The modeling information being supplied should be sufficient to allow an independent modeler to fully corroborate the CALPUFF modeling results.
